Machine learning: Part 5

Deep neural networks (DNN)

- Why deep?
- Avoiding vanishing gradients
- Avoiding overfitting

Y. Liu Intro to AI 1 / 28

^{*}Slides based on those of Pascal Poupart

Representation matters

- The choice of representation has an enormous effect on the performance of machine learning algorithms.
- This dependence on representations is a general phenomenon that appears throughout computer science and even daily life.
- In computer science, operations such as searching a collection of data can proceed exponentially faster if the collection is structured and indexed intelligently.

Representation learning

- Many Al tasks can be solved by designing the right set of features to extract for that task, then providing these features to a simple machine learning algorithm.
- For many tasks, however, it is difficult to know what features should be extracted.
- Manually designing features for a complex task requires a great deal of human time and efforts.
- One solution to this problem is to use machine learning to discover not only the mapping from representation to output but also the representation itself.

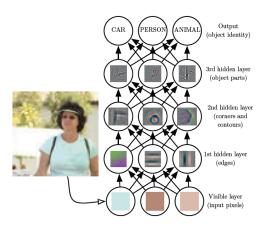

Hierarchical representations

- When designing features, our goal is usually to separate the factors of variation that explain the observed data.
- Such factors are often not quantities that are directly observed.
- Instead, they may exist as either unobserved objects or unobserved forces in the physical world that affect observable quantities.
- They can be thought of as concepts or abstractions that help us make sense of the rich variability in the data.
- When analyzing a speech recording, the factors of variation include the speaker's age, their sex, their accent and the words they are speaking.

Y. Liu Intro to Al 4 / 28

Deep learning

Deep learning enables computers to build complex concepts out of simpler ones.

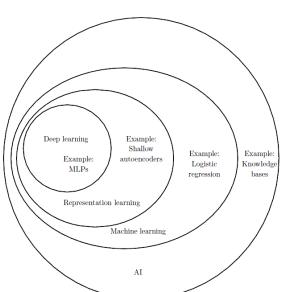

Images here are visualizations of features represented

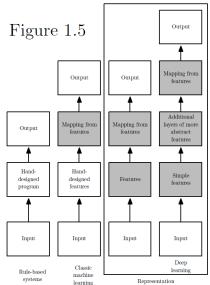

Another perspective

- Depth enables the computer to learn a multistep computer program.
- Each layer of the representation can be thought of as the state of the computer's memory after executing another set of instructions in parallel.
- Networks with greater depth can execute more instructions in sequence.
- Sequential instructions offer great power because later instructions can refer back to the results of earlier instructions.

Machine learning and Al

Machine learning and Al

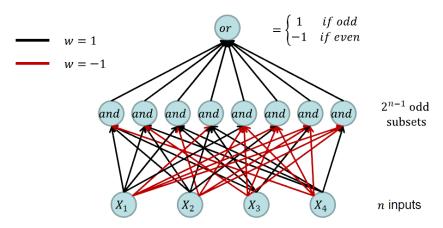

learning

Why deep?

- Universal Approximator Theorem: One hidden layer is enough to represent (not learn) an approximation of any function to an arbitrary degree of accuracy
- However as we increase the number of layers, the number of units needed may decrease exponentially (with the number of layers)

Example – Parity Function

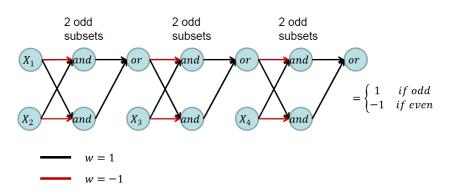

Single layer of hidden nodes

Y. Liu Intro to AI 10 / 28

Example – Parity Function

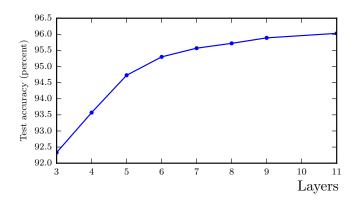

• 2n-2 layers of hidden nodes

Y. Liu Intro to AI 11 / 28

Better Generalization with Greater Depth

Shallow net may overfit more

The brain has a deep architecture

- For example, the visual cortex is well-studied and shows a sequence of areas each of which contains a representation of the input, and signals flow from one to the next.
- Each level of this feature hierarchy represents the input at a different level of abstraction, with more abstract features further up in the hierarchy, defined in terms of the lower-level ones.

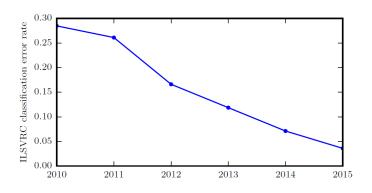

Cognitive processes seem deep

- Humans organize their ideas and concepts hierarchically.
- Humans first learn simpler concepts and then compose them to represent more abstract ones.
- Engineers break-up solutions into multiple levels of abstraction and processing

Breakthrough in Learning Deep Architectures

- Before 2006, attempts at training deep architectures failed
- Three papers changed that in 2006, led by Hinton'ss revolutionary work on Deep Belief Networks
- Key principles are found in all three papers:
 - Unsupervised learning of representations is used to train each layer.
 - The representation learned at each level is the input for the next layer.
 - Use supervised training to fine-tune all the layers

Decreasing error rate over time

Many applications of deep learning

- computer vision, speech and audio processing,
- natural language processing, robotics,
- bioinformatics and chemistry, video games,
- search engines, online advertising and finance

Y. Liu Intro to AI 17 / 28

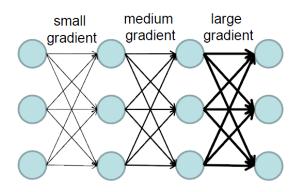

Deep Neural Network

- Definition: neural network with many hidden layers
- Advantage: high expressivity
- Challenges:
 - How should we train a deep neural network?
 - How can we avoid overfitting?

Vanishing gradients (梯度消失)

Gradient descent: $w_{ij} \leftarrow w_{ij} - \alpha \partial Loss / \partial w_{ij}$

Deep neural networks often suffer from vanishing gradients

Avoiding vanishing gradients: Rectified linear units and maxout units

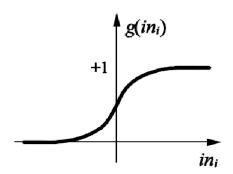

Y. Liu Intro to Al 19 / 28

Sigmoid units

•
$$g(x) = 1/(1 + e^{-x})$$

•
$$g' = g(1-g) \in [0, 0.25]$$

• Derivative is always less than 1

Y. Liu Intro to Al

Simple example

•
$$Y = \sigma \left(W_4 \ \sigma \left(W_3 \ \sigma \left(W_2 \ \sigma (W_1 \ X) \right) \right) \right)$$

$$X \longrightarrow W_1 \longrightarrow W_2 \longrightarrow W_3 \longrightarrow W_4 \longrightarrow Y$$

- Common weight initialization in (-1,1)
- · Sigmoid function and its derivative always less than 1
- This leads to vanishing gradients:

$$\begin{split} \frac{\partial Y}{\partial W_4} &= \sigma'(in_4)\sigma(in_3) \\ \frac{\partial Y}{\partial W_3} &= \sigma'(in_4)W_4\sigma'(in_3)\sigma(in_2) \leq \frac{\partial Y}{\partial W_4} \\ \frac{\partial Y}{\partial W_2} &= \sigma'(in_4)W_4\sigma'(in_3)W_3\sigma'(in_2)\sigma(in_1) \leq \frac{\partial Y}{\partial W_3} \\ \frac{\partial Y}{\partial W_1} &= \sigma'(in_4)W_4\sigma'(in_3)W_3\sigma'(in_2)W_2\sigma'(in_1)X \leq \frac{\partial Y}{\partial W_2} \end{split}$$

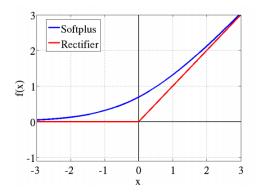

17

Since $W_{i+1}\sigma'(in_i) < \frac{1}{4}$, $\frac{\partial Y}{\partial W_i}$ decreases exponentially with i

Y. Liu

Rectified linear units (ReLU) (整流线性单元)

- g(x) = max(0, x)
- Gradient is 0 or 1
- Soft version: Softplus: $g(x) = \log(1 + e^{-x})$

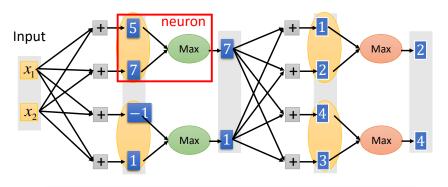

< ロ > ← □

Y. Liu Intro to Al 22 / 28

Maxout units

ReLU is a special cases of Maxout

You can have more than 2 elements in a group.

<ロ > ← □

Y. Liu Intro to AI 23 / 28

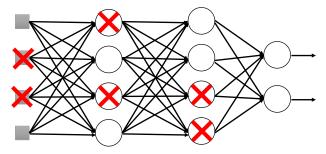

Avoiding overfitting: Dropout

- High expressivity increases the risk of overfitting
 - ullet # of parameters is often larger than the amount of data
- Idea: randomly "drop" some units from the network when training
- Training: at each iteration of gradient descent
 - Each hidden unit is dropped with prob. 0.5
 - Each input unit is dropped with prob. 0.2
- Prediction (testing):
 - Multiply the output of each unit by one minus its drop probability

24 / 28

Dropout

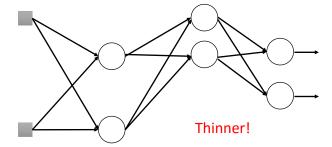

Training:

- > Each time before updating the parameters
 - Each neuron has p% to dropout

Dropout

Training:

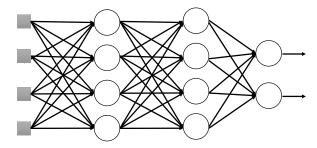

- > Each time before updating the parameters
 - Each neuron has p% to dropout
 - The structure of the network is changed.
 - Using the new network for training

26/28

Dropout

Testing:

No dropout

- If the dropout rate at training is p%, all the weights times (1-p)%
- Assume that the dropout rate is 50%. If a weight w = 1 by training, set w = 0.5 for testing.

Intro to Al

Intuition

- Ensemble learning takes a number of learning algorithms and combines their output to make a prediction.
- Dropout can be viewed as an approximate form of ensemble learning
- In each training iteration, a different subnetwork is trained
- At test time, these subnetworks are merged by averaging their weights
